

New from JAMAR

Collect Travel Time Data Using GPS!

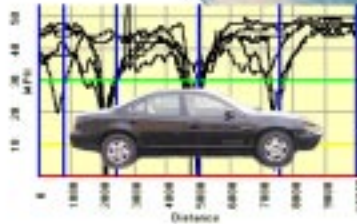

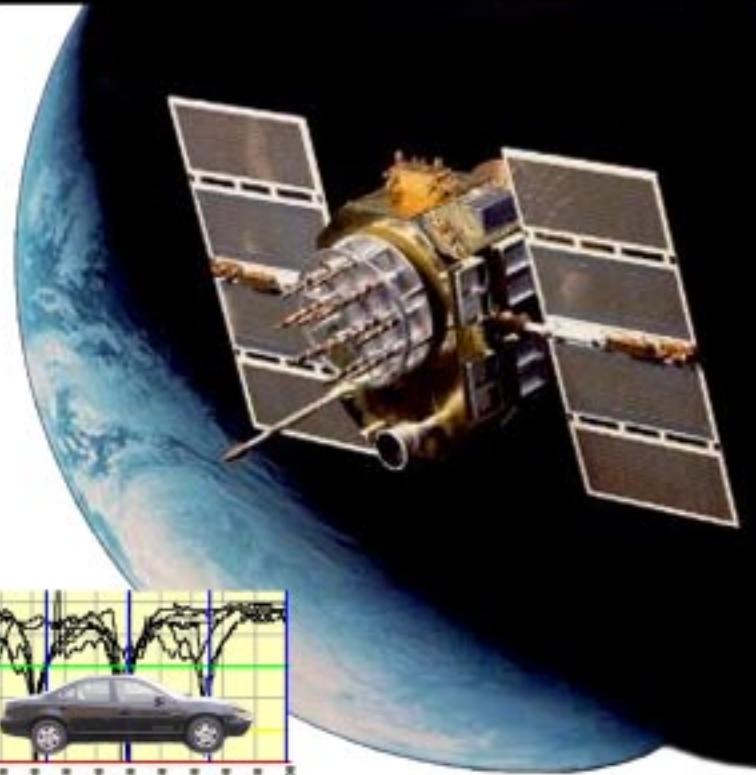

- Identify problem areas where delays occur
- Easily compare before and after results when making changes to signal timings
- No in-vehicle installation required

Our new **GPS interface software** allows you to easily collect data for travel time analysis using a standard GPS receiver and either a laptop or PDA. This data can then be processed to create detailed Travel Time studies with **PC-Travel for Windows**.

Data collection is made easier with GPS since you no longer have to install a transmission sensor and wiring in your vehicle to collect data. Previously, the speed signal from your car was the only way to gather Travel Time data, so only vehicles with this equipment installed could be used. Now, with our GPS software, just about any vehicle can be used.

As you drive, GPS data is sent from the GPS receiver to the laptop or PDA. Our software processes this data to provide time, speed, latitude, longitude, and a variety of other statistics. This data can then be used by PC-Travel for Windows for comprehensive travel time and delay analysis.

PC-Travel allows you to quickly and easily organize your data into individual studies. The program will provide you with the travel time between intersections (or any fixed points), the average speed of travel, the number of stops that occurred, and the total delay. Extensive reports and graphs can then be generated with a click of your mouse!

The screenshot shows the 'GPS Travel Time Data Collector - Version 1.0.5' software interface. It displays a 'Study Name' of 'Test', 'Run 1', and 'Node 2'. Key statistics shown include: Time: 3:36:21, Speed: 28.3, Latitude: 2902.6079 N, Longitude: 08222.7170, Fix: 2, Num Sats: 07, and HDOP: 1.5. A table of data points is also visible, with columns for Time, Speed, Time, Latitude, and Longitude. The interface includes buttons for '(R)un' and '(N)ode'.

Send data directly to a laptop or a PDA!
